Lists in Python

BEGINNER LESSON | Qspiders | Python 3

Learning goals: Create a list, read an item, and replace an item.

1. What is a list?

A list stores multiple items in one value. Write the items inside square brackets `[]`, separated by commas. Python calls this type `list`.

2. Create and use

Indexing starts at `0`. Use an index to read or replace an item.

```
colors = ["red", "blue", "red"]
print(colors[0])  # Output: red
colors[0] = "green"
print(colors)     # Output: ['green', 'blue', 'red']
```

3. Check the type

Use `type()` to find a value's data type.

```
print(type(colors))  # Output: <class 'list'>
```

4. Key points

- Lists keep items in order and allow duplicate items.
- You can replace, add, or remove items after creating a list.
- Index `0` is the first item; index `1` is the second.
- `[]` creates an empty list.

5. Try it yourself

Create a list of three fruits. Print the second fruit, then replace the first fruit.
