Tuples in Python

BEGINNER LESSON | Qspiders | Python 3

Learning goals: Create a tuple, read an item, and recognize its fixed items.

1. What is a tuple?

A tuple stores multiple items, usually written inside parentheses `()`, separated by commas. Python calls this type `tuple`.

2. Create and use

Indexing starts at `0`. Read an item by putting its index inside square brackets.

```
colors = ("red", "blue", "red")
print(colors[0])  # Output: red
print(colors[1])  # Output: blue
```

3. Check the type

Use `type()` to find a value's data type.

```
print(type(colors))  # Output: <class 'tuple'>
```

4. Key points

- Tuples keep items in order and allow duplicate items.
- You cannot replace, add, or remove the items of an existing tuple.
- A one-item tuple needs a comma: `("red",)`. `("red")` is just a string.
- `()` creates an empty tuple.

5. Try it yourself

Create a tuple containing three days. Print its first day and its type.
