Booleans in Python

BEGINNER LESSON | Qspiders | Python 3

Learning goals: Use True and False and recognize the Boolean type.

1. What is a Boolean?

A Boolean has only two possible values: `True` and `False`. It represents a yes/no or true/false state. Python calls this type `bool`.

2. Create and use

Use a Boolean to record whether something is ready, available, or complete.

```
is_ready = True
is_finished = False
print(is_ready)     # Output: True
print(is_finished)  # Output: False
```

3. Check the type

Use `type()` to find a value's data type.

```
print(type(is_ready))  # Output: <class 'bool'>
```

4. Key points

- Use capital `T` and `F`: `True`, `False`.

- Do not put Boolean values inside quotes: `"False"` is text.

- Both `True` and `False` have the same type: `bool`.

5. Try it yourself

Create `is_open` with `True` and print it. Change it to `False` and print it again.
